2.1 Spatial covariances

Valid covariance functions

Bochner's theorem: The class of covariance functions is the class of positive definite functions C:

$$\sum_i \sum_j a_i a_j C(\mathbf{s}_i, \mathbf{s}_j) \geq 0$$

Why?

$$\sum_i \sum_j a_i a_j C(\mathbf{s}_i, \mathbf{s}_j) = \text{Var}(\sum a_i Z(\mathbf{s}_i))$$

Spectral representation

By the spectral representation any isotropic continuous correlation on \mathbb{R}^d is of the form

$$\rho(\mathbf{v}) = \mathbf{E} \left(e^{i\mathbf{u}^T \mathbf{X}} \right), \mathbf{v} = \|\mathbf{u}\|, \mathbf{X} \in \mathbb{R}^d$$

By isotropy, the expectation depends only on the distribution G of $\|\mathbf{X}\|$. Let Y be uniform on the unit sphere. Then

$$\rho(\mathbf{v}) = \mathbf{E} e^{i\mathbf{v}\|\mathbf{X}\|Y} = \mathbf{E} \Phi_Y(\mathbf{v}\|\mathbf{X}\|)$$

Isotropic correlation

$$\Phi_Y(\mathbf{u}) = \left(\frac{2}{\mathbf{u}}\right)^{\frac{d}{2}-1} \Gamma\left(\frac{d}{2}\right) J_{\frac{d}{2}-1}(\mathbf{u})$$

$J_\nu(\mathbf{u})$ is a Bessel function of the first kind and order ν .

Hence

$$\rho(\mathbf{v}) = \int_0^\infty \Phi_Y(s\mathbf{v}) dG(s)$$

and in the case $d=2$

$$\rho(\mathbf{v}) = \int_0^\infty J_0(s\mathbf{v}) dG(s) \quad (\text{Hankel transform})$$

The Bessel function J_0

The exponential correlation

A commonly used correlation function is $\rho(v) = e^{-v/\phi}$. Corresponds to a Gaussian process with continuous but not differentiable sample paths.

More generally, $\rho(v) = c(v=0) + (1-c)e^{-v/\phi}$ has a *nugget* c , corresponding to measurement error and spatial correlation at small distances.

All isotropic correlations are a mixture of a nugget and a continuous isotropic correlation.

The squared exponential

Using $G'(x) = \frac{2x}{\phi^2} e^{-4x^2/\phi^2}$ yields

$$\rho(v) = e^{-\left(\frac{v}{\phi}\right)^2}$$

corresponding to an underlying Gaussian field with analytic paths.

This is sometimes called the Gaussian covariance, for no really good reason.

A generalization is the *power(ed) exponential* correlation function,

$$\rho(v) = \exp\left(-\left[\frac{v}{\phi}\right]^\kappa\right), \quad 0 < \kappa \leq 2$$

The spherical

$$\rho(v) = \begin{cases} 1 - 1.5v + 0.5\left(\frac{v}{\phi}\right)^3; & h < \phi \\ 0, & \text{otherwise} \end{cases}$$

Corresponding variogram

$$\begin{aligned} \text{nugget} &\rightarrow \tau^2 + \frac{\sigma^2}{2} \left(3\frac{t}{\phi} + \left(\frac{t}{\phi}\right)^3 \right); & 0 \leq t \leq \phi \\ \text{sill} &\rightarrow \tau^2 + \sigma^2; & t > \phi \leftarrow \text{range} \end{aligned}$$

variograms with equivalent "practical range"

The Matérn class

$$G'(x) = \frac{2\kappa}{\phi^{2\kappa}} \frac{x}{(x^2 + \phi^{-2})^{1+\kappa}}$$
$$\rho(v) = \frac{1}{2^{\kappa-1}\Gamma(\kappa)} \left(\frac{v}{\phi}\right)^\kappa K_\kappa\left(\frac{v}{\phi}\right)$$

where K_κ is a modified Bessel function of the third kind and order κ . It corresponds to a spatial field with $\kappa-1$ continuous derivatives

$\kappa=1/2$ is exponential;

$\kappa=1$ is Whittle's spatial correlation;

$\kappa \rightarrow \infty$ yields squared exponential.

models with equivalent "practical" range

Some other covariance/variogram families

Name	Covariance	Variogram
Wave	$\sigma^2 \frac{\sin(\phi t)}{\phi t}$	$\tau^2 + \sigma^2 \left(1 - \frac{\sin(\phi t)}{\phi t}\right)$
Rational quadratic	$\sigma^2 \left(1 - \frac{t^2}{1 + \phi t^2}\right)$	$\tau^2 + \frac{\sigma^2 t^2}{1 + \phi t^2}$
Linear	None	$\tau^2 + \sigma^2 t$
Power law	None	$\tau^2 + \sigma^2 t^\phi$

Estimation of variograms

Recall $\gamma(v) = \sigma^2(1 - \rho(v))$

Method of moments: square of all pairwise differences, smoothed over lag bins

$$\bar{\gamma}(h) = \frac{1}{|\mathbf{N}(h)|} \sum_{i,j \in \mathbf{N}(h)} (Z(\mathbf{s}_i) - Z(\mathbf{s}_j))^2$$

$$\mathbf{N}(h) = \left\{ (i, j) : h - \frac{\Delta h}{2} \leq |\mathbf{s}_i - \mathbf{s}_j| \leq h + \frac{\Delta h}{2} \right\}$$

Problems: Not necessarily a valid variogram

Not very robust

A robust empirical variogram estimator

$(Z(x)-Z(y))^2$ is chi-squared for Gaussian data

Fourth root is variance stabilizing

Cressie and Hawkins:

$$\tilde{\gamma}(\mathbf{h}) = \frac{\left\{ \frac{1}{|\mathbf{N}(\mathbf{h})|} \sum |Z(\mathbf{s}_i) - Z(\mathbf{s}_j)|^{1/2} \right\}^4}{0.457 + \frac{0.494}{|\mathbf{N}(\mathbf{h})|}}$$

Least squares

Minimize

$$\theta \mapsto \sum_i \sum_j \left([Z(\mathbf{s}_i) - Z(\mathbf{s}_j)]^2 - \gamma(\|\mathbf{s}_i - \mathbf{s}_j\|; \theta) \right)^2$$

Alternatives:

- **fourth root transformation**
- **weighting by $1/\gamma^2$**
- **generalized least squares**

Maximum likelihood

$$\mathbf{Z} \sim N_n(\boldsymbol{\mu}, \boldsymbol{\Sigma}) \quad \boldsymbol{\Sigma} = \alpha[\rho(\mathbf{s}_i - \mathbf{s}_j; \boldsymbol{\theta})] = \alpha \mathbf{V}(\boldsymbol{\theta})$$

Maximize

$$\begin{aligned} \ell(\boldsymbol{\mu}, \alpha, \boldsymbol{\theta}) = & -\frac{n}{2} \log(2\pi\alpha) - \frac{1}{2} \log \det \mathbf{V}(\boldsymbol{\theta}) \\ & + \frac{1}{2\alpha} (\mathbf{Z} - \boldsymbol{\mu})^T \mathbf{V}(\boldsymbol{\theta})^{-1} (\mathbf{Z} - \boldsymbol{\mu}) \end{aligned}$$

$$\hat{\boldsymbol{\mu}} = \mathbf{1}^T \mathbf{Z} / n \quad \hat{\alpha} = \mathbf{G}(\hat{\boldsymbol{\theta}}) / n \quad \mathbf{G}(\boldsymbol{\theta}) = (\mathbf{Z} - \hat{\boldsymbol{\mu}})^T \mathbf{V}(\boldsymbol{\theta})^{-1} (\mathbf{Z} - \hat{\boldsymbol{\mu}})$$

and $\boldsymbol{\theta}$ maximizes the profile likelihood

$$\ell^*(\boldsymbol{\theta}) = -\frac{n}{2} \log \frac{\mathbf{G}^2(\boldsymbol{\theta})}{n} - \frac{1}{2} \log \det \mathbf{V}(\boldsymbol{\theta})$$

Parana data

A peculiar ml fit

Some more fits

All together now...

Bayesian kriging

Instead of estimating the parameters, we put a prior distribution on them, and update the distribution using the data.

Model: $(\mathbf{Z}|\theta) \sim \mathbf{N}(\beta, \sigma^2 \mathbf{C}(\phi) + \tau^2 \mathbf{I})$

Prior: $f(\theta) = f(\beta)f(\sigma^2)f(\phi)f(\tau^2)$

Posterior:

$$f(\beta|\mathbf{Z} = \mathbf{z}) \propto f(\beta) \iiint f(\mathbf{z}|\theta) f(\sigma^2) f(\phi) f(\tau^2) d\sigma^2 d\phi d\tau^2$$

geoR

Prior is assigned to ϕ and τ/σ . The latter assumed zero unless specified.

The distributions are discretized.

Default prior on mean β is flat (if not specified, assumed constant).

(Lots of different assignments are possible)

Prior/posterior of ϕ

Variogram estimates

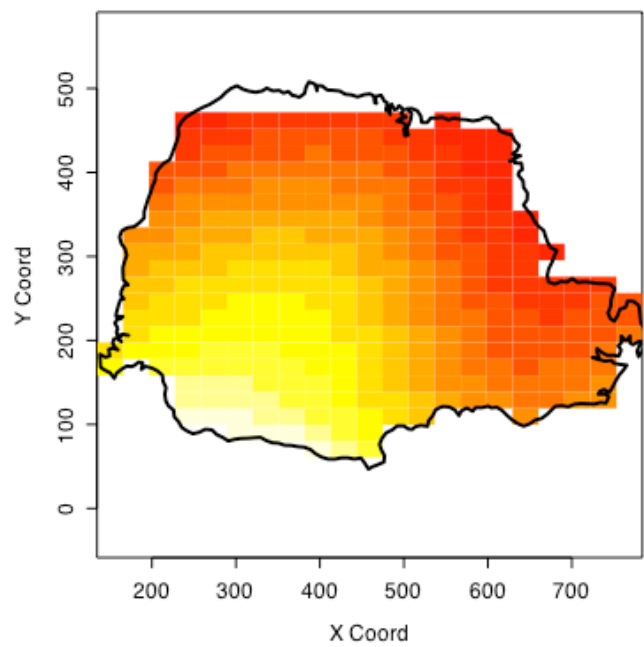

Bayes vs universal kriging

Bayes predictive mean

Universal kriging

Spectral representation

Stationary processes

$$Z(s) = \int_{\mathbb{R}^d} \exp(is^T \omega) dY(\omega)$$

Spectral process Y has stationary increments

$$E|dY(\omega)|^2 = dF(\omega)$$

If F has a density f, it is called the spectral density.

$$\text{Cov}(Z(s_1), Z(s_2)) = \int_{\mathbb{R}^d} e^{i(s_1 - s_2)^T \omega} f(\omega) d\omega$$

Estimating the spectrum

For process observed on $n \times n$ grid,
estimate spectrum by *periodogram*

$$I_{n,n}(\omega) = \frac{1}{(2\pi n)^2} \left| \sum_{j \in J} z(j) e^{i\omega^T j} \right|^2$$
$$\omega = \frac{2\pi j}{n}; \mathbf{J} = \{ \lfloor (n-1)/2 \rfloor, \dots, n - \lfloor (n-1)/2 \rfloor \}^2$$

Equivalent to DFT of sample covariance

Properties of the periodogram

Periodogram values at Fourier frequencies $(j,k)\pi/\Delta$ are

- uncorrelated
- asymptotically unbiased
- not consistent

To get a consistent estimate of the spectrum, smooth over nearby frequencies

Some common isotropic spectra

Squared exponential

$$f(\omega) = \frac{\sigma^2}{2\pi\alpha} \exp(-\|\omega\|^2 / 4\alpha)$$

$$C(r) = \sigma^2 \exp(-\alpha\|r\|^2)$$

Matérn

$$f(\omega) = \phi(\alpha^2 + \|\omega\|^2)^{-\nu-1}$$

$$C(r) = \frac{\pi\phi(\alpha\|r\|)^\nu \mathcal{K}_\nu(\alpha\|r\|)}{2^{\nu-1}\Gamma(\nu+1)\alpha^{2\nu}}$$

A simulated process

$$Z(\mathbf{s}) = \sum_{j=0}^{15} \sum_{k=-15}^{15} g_{jk} \cos \left(2\pi \left[\frac{j s_1}{m} + \frac{k s_2}{n} \right] + U_{jk} \right)$$

$$g_{jk} = \exp(-|j + 6 - k \tan(20^\circ)|)$$

Thetford canopy heights

crown height**

Focus on 32 x 32 subset

Spectrum of canopy heights

Whittle likelihood

Approximation to Gaussian likelihood using periodogram:

$$\ell(\theta) = \sum_{\omega} \left\{ \log f(\omega; \theta) + \frac{I_{N,N}(\omega)}{f(\omega; \theta)} \right\}$$

where the sum is over Fourier frequencies, avoiding 0, and f is the spectral density

Takes $O(N \log N)$ operations to calculate instead of $O(N^3)$.

Using non-gridded data

Consider

$$Y(\mathbf{x}) = \Delta^{-2} \int \mathbf{h}(\mathbf{x} - \mathbf{s}) Z(\mathbf{s}) d\mathbf{s}$$

where

$$\mathbf{h}(\mathbf{x}) = \mathbf{1}(|x_i| \leq \Delta / 2, i = 1, 2)$$

Then Y is stationary with spectral density

$$f_Y(\omega) = \frac{1}{\Delta^2} |\mathbf{H}(\omega)|^2 f_Z(\omega)$$

Viewing Y as a lattice process, it has spectral density

$$f_{\Delta, Y}(\omega) = \sum_{\mathbf{q} \in \mathbb{Z}^2} \left| \mathbf{H}\left(\omega + \frac{2\pi\mathbf{q}}{\Delta}\right) \right|^2 f_Z\left(\omega + \frac{2\pi\mathbf{q}}{\Delta}\right)$$

Estimation

$$\text{Let } Y_{n^2}(\mathbf{x}) = \frac{1}{n_x} \sum_{i \in J_x} h(\mathbf{s}_i - \mathbf{x}) Z(\mathbf{s}_i)$$

where J_x is the grid square with center \mathbf{x} and n_x is the number of sites in the square. Define the tapered periodogram

$$I_{g_1 Y_{n^2}}(\omega) = \frac{1}{\sum g_1^2(\mathbf{x})} \left| \sum g_1(\mathbf{x}) Y_{n^2}(\mathbf{x}) e^{-i\mathbf{x}^T \omega} \right|^2$$

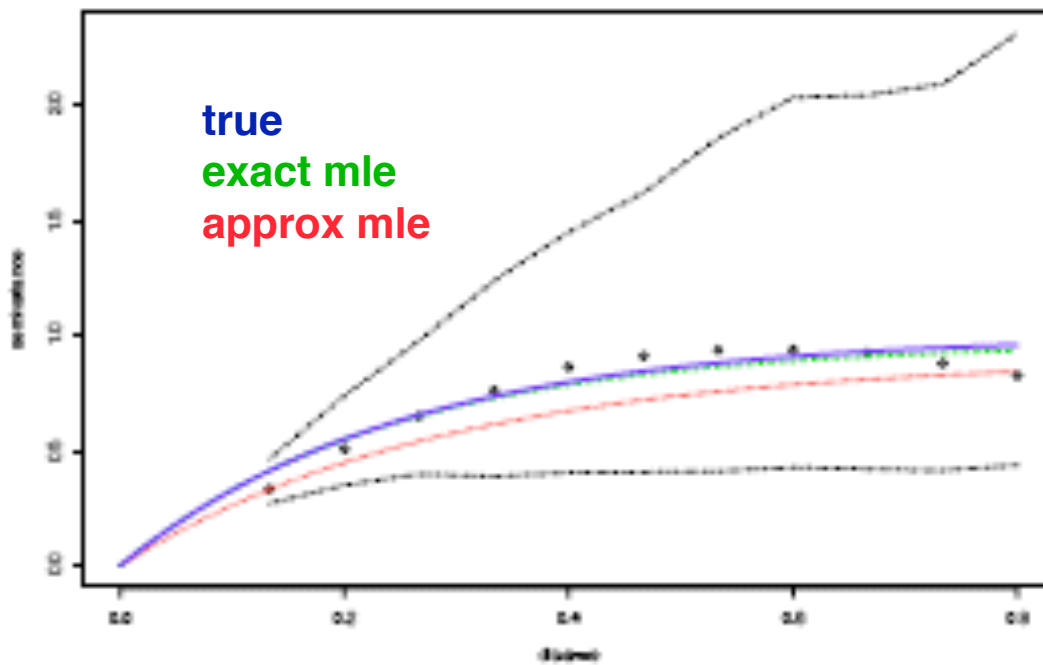

where $g_1(\mathbf{x}) = n_x / \bar{n}$. The Whittle likelihood is approximately

$$\ell_Y = \frac{n^2}{(2\pi)^2} \sum_j \left\{ \log f_{\Delta, Y}(2\pi j / n) + \frac{I_{g_1, Y_{n^2}}(2\pi j / n)}{f_{\Delta, Y}(2\pi j / n)} \right\}$$

A simulated example
