Sliding Windows

- A useful model of stream processing is that queries are about a *window* of length *N* – the *N* most recent elements received
- Interesting case: N is so large that the data cannot be stored in memory, or even on disk
 - Or, there are so many streams that windows for all cannot be stored
- Amazon example:
 - For every product X we keep 0/1 stream of whether that product was sold in the n-th transaction
 - We want answer queries, how many times have we sold X in the last k sales

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

Sliding Window: 1 Stream

Sliding window on a single stream: N = 6

Counting Bits (1)

Problem:

- Given a stream of 0s and 1s
- Be prepared to answer queries of the form
 How many 1s are in the last k bits? where k ≤ N

Obvious solution:

Store the most recent **N** bits

When new bit comes in, discard the N+1st bit

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

5 /

Counting Bits (2)

 You can not get an exact answer without storing the entire window

Real Problem: What if we cannot afford to store N bits?

E.g., we're processing 1 billion streams and
 N = 1 billion
 010011011101010110

-Past

Future

 But we are happy with an approximate answer

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

6/

[Datar, Gionis, Indyk, Motwani]

DGIM Method

 DGIM solution that does <u>not</u> assume uniformity

- We store O(log²N) bits per stream
- Solution gives approximate answer, never off by more than 50%
 - Error factor can be reduced to any fraction > 0, with more complicated algorithm and proportionally more stored bits

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

7/

< □ > < 同 > < 三 > < 三 >

[Datar, Gionis, Indyk, Motwani]

DGIM method

- Idea: Break stream in blocks with specific number of 1s:
 - Let the block *sizes* (number of 1s) increase exponentially
- When there are few 1s in the window, block sizes stay small, so errors are small

DGIM: Timestamps

- Each bit in the stream has a timestamp, starting 1, 2, ...
- (but we only care about timestamps of "1" bits)
- Record timestamps modulo N (the window size), so we can represent any relevant timestamp in O(log₂N) bits

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

9/

(日) (四) (日) (日) (日)

DGIM: Buckets

- A bucket in the DGIM method is a record consisting of:
 - (A) The timestamp of its end [O(log N) bits]
 - (B) The number of 1s between its beginning and end [O(log log N) bits]
- Constraint on buckets: Number of 1s must be a power of 2
 - That explains the O(log log N) in (B) above

Representing a Stream by Buckets

- Either one or two buckets with the same power-of-2 number of 1s
- Buckets do not overlap
- Buckets are sorted by size
 - Earlier buckets are not smaller than later buckets
- Buckets disappear when their end-time is > N time units in the past

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

Marina Meila (UW)

IV Streaming

Example: Bucketized Stream

Three properties of buckets that are maintained:

- Either one or two buckets with the same power-of-2 number of 1s
- Buckets do not overlap in timestamps
- Buckets are sorted by size

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

12

Updating Buckets (1)

- When a new bit comes in, drop the last (oldest) bucket if its end-time is prior to N time units before the current time
- 2 cases: Current bit is 0 or 1
- If the current bit is 0: no other changes are needed

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

13

IV Streaming

CSE 547/STAT 548 Winter 2022

(日) (四) (日) (日) (日)

Updating Buckets (2)

If the current bit is 1:

- (1) Create a new bucket of size 1, for just this bit
 - timestamp = current time
- (2) If there are now three buckets of size 1, combine the oldest two into a bucket of size 2
- (3) If there are now three buckets of size 2, combine the oldest two into a bucket of size 4
- (4) And so on ...

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

14

Marina Meila (UW)

IV Streaming

Example: Updating Buckets

Current state of the stream:

Bit of value 1 arrives

Buckets get merged...

State of the buckets after merging

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

How to Query?

- To estimate the number of 1s in the most recent N bits:
 - 1. Sum the sizes of all buckets but the last

(note "size" means the number of 1s in the bucket)

- 2. Add half the size of the last bucket
- Remember: We do not know how many 1s of the last bucket are still within the wanted window

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

イロト イボト イヨト イヨト

Error Bound: Proof

- Why is error 50%? Let's prove it!
- Suppose the last bucket has size 2^r
- Then by assuming 2^{r-1} (i.e., half) of its 1s are still within the window, we make an error of at most 2^{r-1}
- Since there is at least one bucket of each of the sizes less than 2^r, the true sum is at least 1+2+4+..+2^{r-1} = 2^r-1

Further Reducing the Error

- Instead of maintaining 1 or 2 of each size bucket, we allow either r-1 or r buckets (r > 2)
 - Except for the largest size buckets; we can have any number between 1 and r of those
- Error is at most O(1/r)
- By picking *r* appropriately, we can tradeoff between number of bits we store and the error

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

Extensions

- Can we use the same trick to answer queries How many 1's in the last k? where k < N?</p>
 - A: Find earliest bucket B that at overlaps with k. Number of 1s is the sum of sizes of more recent buckets + ½ size of B

Can we handle the case where the stream is not bits, but integers, and we want the sum of the last k elements?

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org

Extensions

Stream of positive integers

We want the sum of the last k elements

- Amazon: Avg. price of last k sales
- Solution:
 - (1) If you know all have at most m bits
 - Treat m bits of each integer as a separate stream
 - Use DGIM to count 1s in each integer c_i...estimated count for i-th bit
 - The sum is $= \sum_{i=0}^{m-1} c_i 2^i$
 - (2) Use buckets to keep partial sums

Sum of elements in size b bucket is at most 2^b

Idea: Sum in each bucket is at most 2^b (unless bucket has only 1 integer) Bucket sizes:

J. Leskovec, A. Rajaraman, J. Ullman: Mining of Massive Datasets, http://www.mmds.org
