#### A GENERAL MODELING FRAMEWORK

- Let Z(·) be a realization of a spatial stochastic process defined for all s ∈ D ⊂ ℝ<sup>d</sup>, where d is typically equal to 2 or 3
- ▶ We observe the value of  $Z(\cdot)$  at a finite set of locations  $s_1, \ldots, s_n \in D$  and wish to learn about the underlying process
- For all  $\boldsymbol{s} \in \mathcal{D}$ , let

$$Z(\boldsymbol{s}) = \mu(\boldsymbol{s}) + \boldsymbol{Y}(\boldsymbol{s}) + \epsilon(\boldsymbol{s})$$

#### where

- $\mu(\cdot)$  is a deterministic mean function
- $Y(\cdot)$  is a mean-zero latent spatial process
- $\epsilon(\cdot)$  is a spatially independent error process, which is assumed to be independent of  $Y(\cdot)$

Definition A process is said to be second-order stationary if

$$\mathsf{E}[Y(\boldsymbol{s})] = \mathsf{E}[Y(\boldsymbol{s} + \boldsymbol{h})] = \mu$$

and

 $\operatorname{cov}[Y(s), Y(s+h)] = \operatorname{cov}[Y(0), Y(h)] = C(h)$ where the function C(h),  $h \in \mathbb{R}^d$  is called the covariance function

 $\rightarrow$  Here,  $Y(\cdot)$  is a nonstationary spatial process with covariance function  $C(s_1, s_2) = \operatorname{cov}(Y(s_1), Y(s_2))$ 

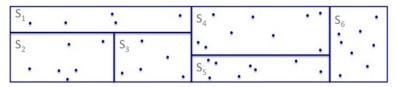

- We focus on modeling  $C(s_1, s_2)$ :
  - 1. has to be a valid covariance function
  - 2. has to be estimable (perhaps from only a single realization of the process)
- ► Following Sampson (2010)'s categorization, the following are a few approaches in the literature...
  - 1. Smoothing and weighted-average methods
  - 2. Basis function methods
  - 3. Process convolutions / spatially-varying parameters

#### 1. SMOOTHING / WEIGHTED-AVERAGE METHODS

**Idea:** Construct a nonstationary spatial process by smoothing several locally stationary processes

An example: (Fuentes, 2001):

- Divide the spatial region  $\mathcal{D}$  into k disjoint subregions  $S_i$ , for i = 1, ..., k, such that  $\mathcal{D} = \bigcup_{i=1}^k S_i$
- Let  $Y_1(\cdot), Y_2(\cdot), \ldots, Y_k(\cdot)$  be stationary spatial processes associated with each of the subregions, with covariance functions estimated using the observations in each subregion

- Construct a global nonstationary process as a weighted average of the locally stationary processes:

$$Y(\boldsymbol{s}) = \sum_{i=1}^{k} w_i(\boldsymbol{s}) Y_i(\boldsymbol{s}),$$

where  $w_i(s)$  is weight function based on the distance between s and the 'center' of region  $S_i$ 

- The number of subregions is chosen using BIC

#### Some other approaches:

- Fuentes and Smith (2002) propose a continuous extension of the original model where

$$Y(s) = \int_{\mathcal{D}} w(s - u) Y_{\theta(u)}(s) du$$

- Nott and Dunsmuir (2002) propose letting

$$C(Y(\boldsymbol{s}_1), Y(\boldsymbol{s}_2)) = \Sigma_0 + \sum_{i=1}^k \underbrace{w_i(\boldsymbol{s}_1)w_i(\boldsymbol{s}_2)C_{\theta_i}(\boldsymbol{s}_1 - \boldsymbol{s}_2)}_{\text{local residual covariance structure}}$$

- Guillot et al. (2001) propose a nonparametric kernel estimator of a nonstationary covariance matrix
- Kim, Mallick, and Holmes (2005)'s approach automatically partitions the spatial domain into disjoint regions and then fits a piecewise Gaussian process model

2. BASIS FUNCTION MODELS

Idea: decompose spatial covariance functions in terms of basis functions

#### An example: EOFs

- The Karhunen-Loéve (K-L) expansion of a covariance function is

$$C_{\mathbf{Y}}(\mathbf{s}_1,\mathbf{s}_2) = \sum_{k=1}^{\infty} \lambda_k \phi_k(\mathbf{s}_1) \phi_k(\mathbf{s}_2)$$

where  $\{\phi_k(\cdot) : k = 1, ..., \infty\}$  and  $\{\lambda_k : k = 1, ..., \infty\}$  are the eigenfunctions and eigenvalues, respectively, of the Fredholm integral equation:

$$\int_{\mathcal{D}} C_{Y}(\boldsymbol{s}_{1}, \boldsymbol{s}_{2}) \phi_{k}(\boldsymbol{s}) d\boldsymbol{s} = \lambda_{k} \phi_{k}(\boldsymbol{s}_{2})$$

- Using this expansion, we can write the process as

$$Y(\boldsymbol{s}) = \sum_{k=1}^{\infty} a_k \phi_k(\boldsymbol{s}).$$

- It can be shown that the truncated decomposition

$$Y_p(\boldsymbol{s}) = \sum_{k=1}^p a_k \phi_k(\boldsymbol{s})$$

is optimal in the sense that it minimizes the variance of the truncation error among all sets of basis function representations of  $Y(\cdot)$  of order p.

- The  $\phi_k(s)$ s can be obtained numerically by solving the Fredholm integral equation (can be difficult).

- An alternative solution when repeated observations of the spatial process (e.g., over time) are available: perform a principal components analysis of the empirical covariance matrix

That is, if  $\hat{\Sigma}_Y$  is the empirical covariance matrix, we can solve the eigensystem

$$\hat{\boldsymbol{\Sigma}}_{\boldsymbol{Y}} \boldsymbol{\Phi} = \boldsymbol{\Phi} \boldsymbol{\Lambda},$$

where

- $\Phi$  is the matrix of eigenvectors  $\rightarrow$  called the "empirical orthogonal functions" or EOFs
- $\boldsymbol{\Lambda}$  is the diagonal matrix with corresponding eigenvalues on the diagonal

- We can use  $\Phi \alpha$  in place of  $\mathbf{Y} = (Y(\mathbf{s}_1), \dots, Y(\mathbf{s}_n))'$ , where  $\alpha = (\alpha_1, \dots, \alpha_n)'$  are a collection of unknown parameters
  - $\rightarrow\,$  typically, truncated version of this approach are used for dimension reduction

#### Advantages of using EOFs:

1. naturally nonstationary

Disadvantages of using EOFs:

- 1. prediction
- 2. measurement error

#### Some other examples:

- Holland et al. (1998) represents a nonstationary spatial covariance function as the sum of a stationary model and a finite sum of EOFs
- Nychka (2002) uses multiresolution wavelets instead of EOFs for computational reasons. More recent work by Matsuo, Nychka, and Paul (2008) has extended the approach to handle irregularly spaced data
- Pintore and Holmes (2004) and Stephenson et al. (2005) induce nonstationarity by evolving the stationary power spectrum with a latent spatial power process
- Katzfuss (2014) propose a model with a low-rank representation of a nonstationary Matérn (with covariance tapering) model for computational considerations

# 3. PROCESS CONVOLUTION MODELS / SPATIALLY-VARYING PARAMETERS

**Idea:** use a constructive specification of a (Gaussian) process to introduce nonstationarity

An example: (Higdon, 1998)

- Let  $k(\cdot): \mathbb{R}^d \to \mathbb{R}$  be a function satisfying

$$\int_{\mathbb{R}^d} k(oldsymbol{u}) doldsymbol{u} < \infty \quad ext{and} \quad \int_{\mathbb{R}^d} k^2(oldsymbol{u}) doldsymbol{u} < \infty$$

and  $W(\cdot)$  denotes *d*-dimensional Brownian motion.

- It can be shown that the process

$$Y(\boldsymbol{s}) = \int_{\mathbb{R}^d} k_{\boldsymbol{s}}(\boldsymbol{u}) W(d\boldsymbol{u})$$

is Gaussian with E[Y(s)] = 0 and

$$C_{Y}(\boldsymbol{s}_{1},\boldsymbol{s}_{2}) = \operatorname{cov}[Y(\boldsymbol{s}_{1}),Y(\boldsymbol{s}_{2})] = \int_{\mathbb{R}^{d}} k_{\boldsymbol{s}_{1}}(\boldsymbol{u})k_{\boldsymbol{s}_{2}}(\boldsymbol{u})d\boldsymbol{u}$$

for  $\pmb{s} \in \mathcal{D} \subset \mathbb{R}^d$ 

- Higdon (1998) proposes a discrete approximation to a nonstationary Gaussian process:

$$Y(\boldsymbol{s}) = \sum_{i=1}^{k} k_{\boldsymbol{s}}(\boldsymbol{u}_i) x_i$$

where the  $x_i$ 's are i.i.d. N(0,  $\lambda^2$ ) random variables associated with each knot location  $u_i$ .

 Higdon (1998) proposes using this model for North Atlantic ocean temperatures. In this model, the kernels were weighted averages of fixed 'basis kernels'

$$Y(\boldsymbol{s}) = \sum_{i=1}^{k} k \boldsymbol{s}(\boldsymbol{u}_i) x_i$$

where

$$k_{\boldsymbol{s}}(\boldsymbol{u}_i) = \sum_{j=1}^{8} w_j(\boldsymbol{s}) k_{\boldsymbol{s}_j^*}(\boldsymbol{u}_i)$$

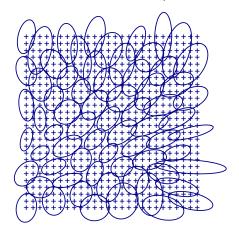

$$w_j(\mathbf{s}) \propto \exp\left(-rac{1}{2}||\mathbf{s} - \mathbf{s}_j^*||^2
ight)$$

 $k_{\boldsymbol{s}_{j}^{*}}(\boldsymbol{u}_{i}) = \frac{1}{\sqrt{2\pi}} |\boldsymbol{\Sigma}_{\boldsymbol{s}_{j}^{*}}|^{-1} \exp\left(-\frac{1}{2}(\boldsymbol{s}_{j}^{*} - \boldsymbol{u}_{i})'\boldsymbol{\Sigma}_{\boldsymbol{s}_{j}^{*}}^{-1}(\boldsymbol{s}_{j}^{*} - \boldsymbol{u}_{i})\right)^{(\text{Higdon, 1998})}$ 

#### Some other examples:

 Kernel parameters can vary smoothly in space (Higdon, Swall, and Kern, 1999; Paciorek and Schervish, 2006):

 Paciorek and Schervish (2006) use this idea to develop a general class of nonstationary covariance functions (including the Matérn model):

$$C(s_1, s_2) = \sigma^2 |\mathbf{\Sigma}_1|^{1/4} |\mathbf{\Sigma}_2|^{1/4} \left| \frac{\mathbf{\Sigma}_1 + \mathbf{\Sigma}_2}{2} \right|^{-1/2} g(-\sqrt{Q_{12}})$$

where

$$Q_{12} = (\boldsymbol{s}_1 - \boldsymbol{s}_2)' \left(rac{\boldsymbol{\Sigma}_1 + \boldsymbol{\Sigma}_2}{2}
ight)^{-1} (\boldsymbol{s}_1 - \boldsymbol{s}_2)$$

and  $g(\cdot)$  is a valid isotropic correlation function

This model allows locally-varying geometric anisotropies  $\rightarrow$  more on this model in the practicum

- Stein (2005) and Anderes and Stein (2011) extend the Paciorek and Schervish (2006) model to allow spatially-varying variance and smoothness parameters
- Kleiber and Nychka (2012) further extend this model to the multivariate setting
- Calder (2007, 2008) proposes space-time versions of the Hidgon model
- Heaton (2014) extends process convolution models to spherical spatial domains

#### SUMMARY

- lots of models  $\rightarrow$  some have been well studied, some haven't
- very little work on model comparison
- with the exception of the basis function models, computation is a BIG challenge
- no general software
- recent work has focused on understanding the reasons for nonstationarity (e.g., covariates)
